Data Sheet

CLC1020

General Purpose, Rail to Rail Output Amplifier
Rail to Rail Amplifiers

FEATURES

- 127µA supply current
- 2.1MHz gain bandwidth
- Input voltage range with 5V supply: -0.4V to 4.3V
- Output voltage range with 5V supply: 0.01V to 4.99V
- 2.7V/µs slew rate
- 0.7pA bias current
- 0.1mV input offset voltage
- No crossover distortion
- Fully specified at 2.7V and 5V supplies
- Pb-free TSOT-5

APPLICATIONS

- Portable/battery-powered applications
- Mobile communications, cell phones, pagers
- ADC buffer
- Active filters
- Portable test instruments
- Medical Equipment
- Portable medical instrumentation

General Description

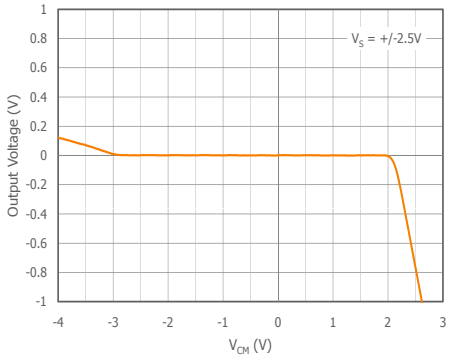
The COMLINEAR CLC1020 is a single channel, high-performance, voltage feedback amplifier. The CLC1020 provides 2.1MHz gain bandwidth product and 2.7V/µs slew rate making it well suited for high-performance battery powered-systems. This COMLINEAR high-performance amplifier also offers low input offset voltage and low bias current.

The COMLINEAR CLC1020 consumes only 127µA supply current and is designed to operate from a supply range of 2.7V to 5.5V (±1.35 to ±2.75). The input voltage range extends 400mV below the negative rail and 700mV below the positive rail. The CLC1020 amplifier operates over the extended temperature range of -40°C to +125°C.

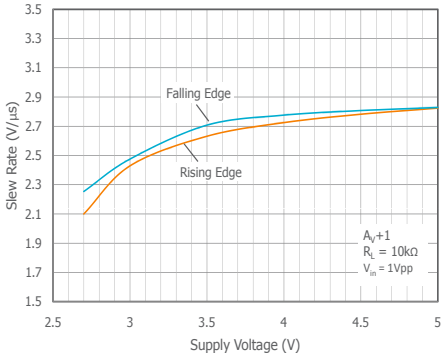
The CLC1020 is packaged in the space saving TSOT-5 package. The TSOT-5 package is pin compatible with the SOT23-5 package.

Typical Performance Examples

Vout vs. Vcm



Slew Rate vs. Supply Voltage



Ordering Information

Part Number	Package	Pb-Free	RoHS Compliant	Operating Temperature Range	Packaging Method
CLC1020IST5X	TSOT-5	Yes	Yes	-40°C to +125°C	Reel

Moisture sensitivity level for all parts is MSL-1.

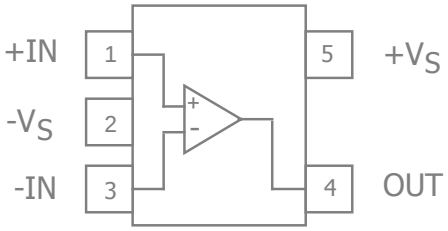
CLC1020 Pin Configuration



CLC1020 Pin Assignments

Pin No.	Pin Name	Description
1	+IN	Output
2	$-V_S$	Negative supply
3	-IN	Positive input
4	OUT	Negative input
5	$+V_S$	Positive supply

Absolute Maximum Ratings

The safety of the device is not guaranteed when it is operated above the "Absolute Maximum Ratings". The device should not be operated at these "absolute" limits. Adhere to the "Recommended Operating Conditions" for proper device function. The information contained in the Electrical Characteristics tables and Typical Performance plots reflect the operating conditions noted on the tables and plots.

Parameter	Min	Max	Unit
Supply Voltage		7	V
Input Voltage Range	$-V_S$-0.4V	$+V_S$	V
Continuous Output Current	Output is protected against momentary short circuit		

Reliability Information

Parameter	Min	Typ	Max	Unit
Junction Temperature			150	°C
Storage Temperature Range	-65		150	°C
Lead Temperature (Soldering, 10s)			260	°C
Package Thermal Resistance				
5-Lead TSOT		221		°C/W

Notes:
Package thermal resistance (θ_{JA}), JDEC standard, multi-layer test boards, still air.

ESD Protection

Application Information

General Description

The CLC1020 is a single supply, general purpose, voltage-feedback amplifier fabricated on a CMOS process. The CLC1020 offers 2.1MHz gain bandwidth product, 2.7V/µs slew rate, and only 127µA supply current. It features a rail to rail output stage and is unity gain stable.

The common mode input range extends to 400mV below ground and to 700mV below Vs. Exceeding these values will not cause phase reversal. However, if the input voltage exceeds the rails by more than 0.5V, the input ESD devices will begin to conduct. The output will stay at the rail during this overdrive condition.

The output stage is short circuit protected and offers "soft" saturation protection that improves recovery time. Figures 1, 2, and 3 illustrate typical circuit configurations for non-inverting, inverting, and unity gain topologies for dual supply applications. They show the recommended bypass capacitor values and overall closed loop gain equations. Figure 4 shows the typical non-inverting gain circuit for single supply applications

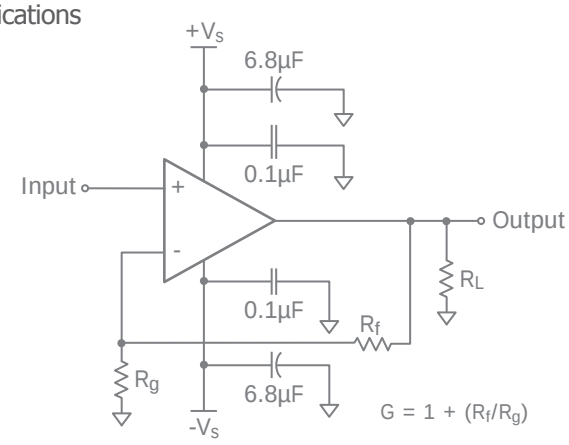

Figure 1. Typical Non-Inverting Gain Circuit

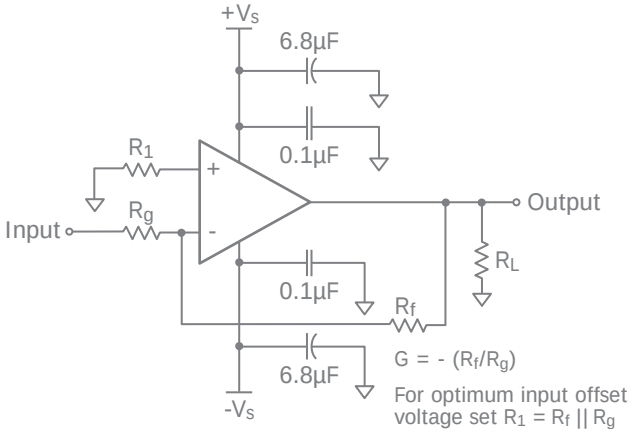

Figure 2. Typical Inverting Gain Circuit

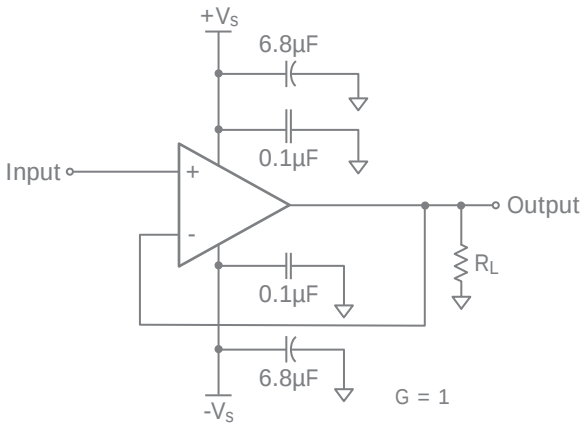

Figure 3. Unity Gain Circuit

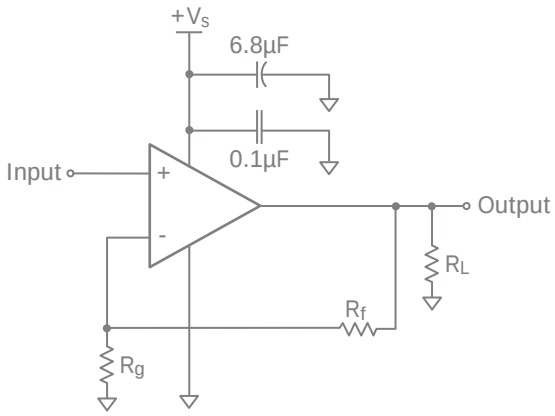

Figure 4. Single Supply Non-Inverting Gain Circuit

Power Dissipation

Power dissipation should not be a factor when operating under the stated 2kΩ load condition. However, applications with low impedance, DC coupled loads should be analyzed to ensure that maximum allowed junction temperature is not exceeded. Guidelines listed below can be used to verify that the particular application will not cause the device to operate beyond its intended operating range.

Maximum power levels are set by the absolute maximum junction rating of 150°C. To calculate the junction temperature, the package thermal resistance value ThetaJA (Θ_{JA}) is used along with the total die power dissipation.

$$T_{Junction} = T_{Ambient} + (\Theta_{JA} \times P_D)$$

Where $T_{Ambient}$ is the temperature of the working environment.

In order to determine P_D, the power dissipated in the load needs to be subtracted from the total power delivered by

the supplies.

$$P_D = P_{supply} - P_{load}$$

Supply power is calculated by the standard power equation.

$$P_{supply} = V_{supply} \times I_{RMS\ supply}$$

$$V_{supply} = V_{S+} - V_{S-}$$

Power delivered to a purely resistive load is:

$$P_{load} = ((V_{LOAD})_{RMS^2})/Rload_{eff}$$

The effective load resistor ($Rload_{eff}$) will need to include the effect of the feedback network. For instance,

$Rload_{eff}$ in Figure 3 would be calculated as:

$$R_L \,||\, (R_f + R_g)$$

These measurements are basic and are relatively easy to perform with standard lab equipment. For design purposes however, prior knowledge of actual signal levels and load impedance is needed to determine the dissipated power. Here, P_D can be found from

$$P_D = P_{Quiescent} + P_{Dynamic} - P_{Load}$$

Quiescent power can be derived from the specified I_S values along with known supply voltage, V_{SUPPLY}. Load power can be calculated as above with the desired signal amplitudes using:

$$(V_{LOAD})_{RMS} = V_{PEAK} / \sqrt{2}$$

$$(I_{LOAD})_{RMS} = (V_{LOAD})_{RMS} / Rload_{eff}$$

The dynamic power is focused primarily within the output stage driving the load. This value can be calculated as:

$$P_{DYNAMIC} = (V_{S+} - V_{LOAD})_{RMS} \times (I_{LOAD})_{RMS}$$

Assuming the load is referenced in the middle of the power rails or Vsupply/2.

The CLC1020 is short circuit protected. However, this may not guarantee that the maximum junction temperature (+150°C) is not exceeded under all conditions.

Driving Capacitive Loads

Increased phase delay at the output due to capacitive loading can cause ringing, peaking in the frequency response, and possible unstable behavior. Use a series resistance, R_S, between the amplifier and the load to help improve stability and settling performance. Refer to Figure 5.

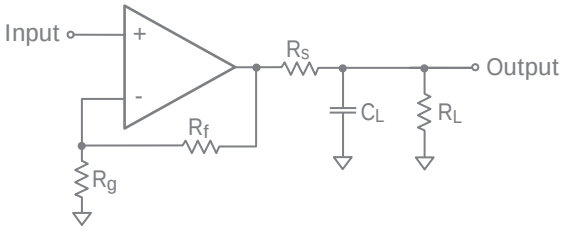

Figure 5. Addition of R_S for Driving Capacitive Loads

For a given load capacitance, adjust R_S to optimize the tradeoff between settling time and bandwidth. In general, reducing R_S will increase bandwidth at the expense of additional overshoot and ringing.

Overdrive Recovery

An overdrive condition is defined as the point when either one of the inputs or the output exceed their specified voltage range. Overdrive recovery is the time needed for the amplifier to return to its normal or linear operating point. The recovery time varies, based on whether the input or output is overdriven and by how much the range is exceeded. The CLC1020 and will typically recover in less than 5us from an overdrive condition. Figure 6 shows the CLC1020 in an overdriven condition.

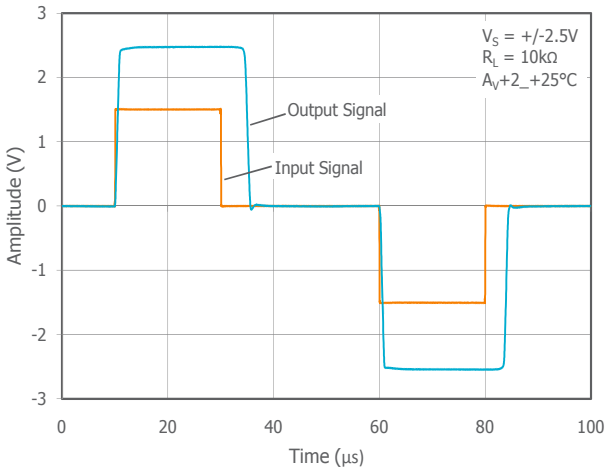

Figure 6. Overdrive Recovery

Layout Considerations

General layout and supply bypassing play major roles in high frequency performance. CADEKA has evaluation boards to use as a guide for high frequency layout and as an aid in device testing and characterization. Follow the steps below as a basis for high frequency layout:

- Include 6.8µF and 0.1µF ceramic capacitors for power

supply decoupling

- Place the 6.8µF capacitor within 0.75 inches of the power pin
- Place the 0.1µF capacitor within 0.1 inches of the power pin
- Remove the ground plane under and around the part, especially near the input and output pins to reduce parasitic capacitance
- Minimize all trace lengths to reduce series inductances

Evaluation Board Information

The following evaluation boards are available to aid in the testing and layout of these devices:

Evaluation Board	Products
CEB004	CLC1020 in TSOT

Evaluation Board Schematics

Evaluation board schematics and layouts are shown in Figures 7-11. These evaluation boards are built for dual supply operation. Follow these steps to use the board in a single-supply application:

1. Short -Vs to ground.

2. Use C3 (6.8µF) and C4 (0.1µF), if the $-V_S$ pin of the amplifier is not directly connected to the ground plane.
